
Aim : -

To implement a Merkle Tree in Java that generates a root hash by recursively hashing transaction data, ensuring secure and efficient verification of data integrity.

Procedure : -

A **Merkle Tree** (also known as a **Hash Tree**) is a binary tree data structure in which:

- **Leaf nodes** contain the hash of individual data elements (e.g., transactions).
- **Non-leaf (internal) nodes** contain the hash of the concatenation of their child node hashes.

In this implementation:

- The input is a list of transactions (strings).
- Each transaction is hashed using **SHA-256** to create the leaf nodes.
- Pairs of hashes are concatenated and then hashed again to form parent nodes.
- This process continues recursively until a single root hash (Merkle Root) is produced.

Working Steps: -

1. Accept a list of transactions as input.
2. Compute the SHA-256 hash of each transaction.
3. Group adjacent hashes in pairs.
4. Concatenate each pair and compute the SHA-256 hash again.
5. Repeat the process level by level until only one hash remains – the **Merkle Root**.
6. Store the entire Merkle Tree structure in a list for reference.

AIM:

To create a block structure that securely stores transaction data in a blockchain system. Each block holds a set of recent transactions that are yet to be validated. Once validated, the block is closed and linked to the previous block, forming a chain. New blocks are generated when validators or miners successfully verify the encrypted information in the block header.

Procedure : -

A **Block** is a fundamental component of a blockchain. It is a data structure that securely stores information such as transactions, timestamps, and a reference to the previous block. Each block is uniquely identified using a cryptographic hash.

In this implementation:

- Each block has an **index**, **timestamp**, **data**, **previous hash**, and a **nonce** (used in mining).
- The **SHA-256** hashing algorithm is used to calculate the block's hash based on its contents.
- A **mining** process is included to simulate Proof-of-Work, where the hash must meet a specified difficulty (number of leading zeros).

Working Steps : -

1. Initialize the block with index, previous hash, and data.
2. Generate a timestamp and set nonce to 0.
3. Calculate the initial hash using SHA-256.
4. Mine the block by adjusting the nonce until the hash starts with the required number of zeros (difficulty).

5. Print the mined block details: index, timestamp, previous hash, current hash, and data.
